Destructor

A destructor is a special member function in C++ that is automatically executed when an object goes out of the scope or is directly ~~deleted~~ deleted.

It is primarily used to released resource like memory, file handles, or network connections.

→ Key features of Destructor:

1.) Same name as the class but prefixed with ~

- If a class is named My-name, the destructor will be ~My-name().

2.) No ~~return~~ return type

3.) No parameters

4.) Automatically called

Syntax:

```
Class My-name
  {
    public:
      ~My-name()
      {
        Cout<<"Destructor called";
      }
  };
```

Akash

Eg;

```
#include<iostream>
using namespace std;
class student
{
    public:
    // Constructor
    student()
    {
        cout<<"constructor called"<<endl;
    }
    // destructor
    ~student()
    {
        cout<<"destructor called";
    }
};
int main()
{
    Student s; // Constructor is called

    /* destructor is automatically called
       when object 's' is goes out of
       scope */
}
```
